## TECHNICAL DESCRIPTION OF THE "QUAD DECODER"

**Introduction.**

The Quad decoder section uses the combined set TDA4650 / TDA4661 / TDA4670 for luminance and chrominance handling and the TDA9045 for automatic gain control.

The TDA4661 comprises two horizontal sync locked CCD (Charged Coupled Devices) delay lines (64  $\mu$ S) working in NTSC as a 'comb filter', as propagation delay line in PAL and as simple delay lines in SECAM.

Cross colour is minimised in SECAM as at the outputs of the colour chip TDA4650 only one colour difference signal is available at one time.

The TDA4670 comprises the luminance delay line, the enhancing or sharpness control and improves the transient of the colour signals. This chip is I<sup>2</sup>C-bus controlled.

**A. Video composite.**

The video composite is AC coupled at pin 2 and pin 12 of the automatic gain control IC TDA9045. Depending on the position of the switch S800 (to bypass the AGC circuit), the output video signal at pin 18 or the video signal at pin 6, arrives at the buffer Q809 where it is AC coupled and available at the emitter on a correct DC level.

For the operation of the AGC circuit, delivering a constant output signal at pin 6 on a constant black level, two pulses are needed:

- the SC/Clamping pulse (to be applied to pin 10). This pulse is generated on the Sync module 76 2226 (see description mentioned module).
- the composite Sync signals 'CS\_INV'. These pulses are generated by the IC LM1881 'Sync Separator', output pin 1, which is buffered-inverted by IC18, output 2, and thereafter via emitter follower Q19, called 'CS\_INV'.

This buffer, transistor Q809, feeds the emitter followers Q804 and Q8067 - Q807 respectively for the chrominance and luminance filters.

**Luminance :**

The colour subcarrier is rejected with L804 / C832 for Pal / SECAM and N4 or with L805 / C833, tuned at 3.58 Mhz for NTSC 3.58.

Note that both transistors Q806 and Q807 are blocked in SVideo (Transistor Q808 is conducting in the SVideo mode whereas its emitter voltage blocks the mentioned transistors).

A next buffer Q805 supplies the Yin input of the TDA4670 through the capacitor C846.

In the first stage of this chip the signal is clamped to the black level and then reduced to a suitable level for the following delay line. This delay line consists of 13 all-pass cells (cell = 90 nS) which are built with gyrators.

This delay time is switchable via the I<sup>2</sup>C bus. A peaking (sharpness control) is incorporated with two selectable centre frequencies (2.6 and 5 Mhz). This circuit consists of two additional delay cells, two 0.5 gain inverting amplifiers and a summation stage.

For better noise reduction the peaking signal is applied via a coring stage and a switchable amplifier before being added to the main signal. The grade of peaking can be controlled by means of the I<sup>2</sup>C bus commands.

**Chrominance :**

The chrominance is filtered by one of the chrominance filters Pal / N4 (L801/C802) or Secam (L800/C800) and via the respective emitter followers Q801 or Q800 applied via C809 to pin 15 of the colour chip TDA4650. In case of N3 the filter L801/C802 is tuned to 3.58 Mhz with C806, switched with Q802.

The chip identifies and demodulates PAL, SECAM, NTSC 3.58 and NTSC 4.43 chrominance signals. The automatic standard recognition by sequential inquiry secures SECAM identification at 50 Hz only, with PAL priority.

The system identification part scans during 4 vertical periods the colour in the sequence Pal / Secam / N3 / N4. Four switched outputs for chrominance filter selection are available at the pins 28 - 25. Note that, by applying an external +9 volts to the appropriated pin the chip can be forced into one colour.

**a) The delay line chip TDA4661 :**

The delay line chip consists of :

- a) two delay lines of 64  $\mu$ S based upon a switched capacitor technique (CCD). These have normal delay function for PAL and SECAM, and a comb filter function for NTSC to avoid chrominance cross colour.
- b) An internal clock of 3 Mhz for the shift register delay lines, derived from a 6 Mhz VCO, which is locked to the line frequency with a sandcastle pulse at pin 5. This means absolutely alignment free.  
A divider by 192 provides a clamp pulse for the input circuits.  
Sample and hold low-pass filters behind the delay lines suppress the clock signal.  
The delayed and undelayed signals are added and fed to the output pins 11, 12 via a buffer stage.

By adding two subsequent lines in SECAM, and as one of these lines is blanked (line sequential blanking), we get at any time the two color difference signals at the respective outputs.

**b) SECAM.**

For SECAM an amplitude limiting circuit is active before quadratic modulation.

The signal amplitude and H/2 content of the colour difference signals (R-Y) and (B-Y) is dependent on the characteristics of the external tuned circuit at pins 7, 8, 9 and 10.

The resonance frequency of this external circuit is adjusted in that way that the demodulated  $F_o$  - carrier is zero for the (B-Y), with L803.

Now, by adjusting the quality factor of the circuit with P800, it is possible to get zero output for the (R-Y)  $F_o$  carrier (un-modulated carrier).

De-emphasis is applied with internal resistors and tuned to the correct value with the capacitors at pins 4 and 2.

The colour difference signals are line sequentially (each two lines) blanked to a level equal to the black signal (black) level.

By this measure only one colour signal is available at any time at the output of the colour chip in order to reduce colour crosstalk.

### c) PAL / NTSC .

The 8 Mhz X-tal is connected at pin 21 and tuned with C813, the 7.2 Mhz X-tal for NTSC 3.58 Mhz is connected at pin 19 and tuned with C812. They can be adjusted to the centre frequency "fo" when the service pin 17 is below the 0.5 volts level (burst off).

The PAL switching stage (correction of the [R-Y] polarity) is disabled in NTSC and on the other hand the phase shifting or Hue is disabled for PAL.

With the delay lines the delayed and undelayed signals are added to compensate propagation shifts, or to obtain the correct colours.

In NTSC, adding delayed and undelayed signals means that the luminance is suppressed on condition the chrominance is same for two subsequent lines.

The delay lines here behave as a 'comb' filter.

### d) Transient improvement

The regulated (R-Y) and (B-Y) signals from IC801 TDA4661 are now sent to the CTI chip TDA4670 for improving the transient time of these chroma signals. This is performed as follows :

Both colour difference channels consist of a clamping stage at the input, a buffer amplifier, a storage stage and an output amplifier. The storage, which is operated by a differential amplifier, stores the colour difference signal during the transient time of the input signal and then switches rapidly to accept the new signal.

A signal formed by differentiating, full wave rectifying and summing the two colour difference signals is compared with a reference signal. The resultant signal is used to switch the sample-and-hold circuits.

Note that the colour transient improvement function can be switched off or on by means of the I<sup>2</sup>C-bus commands (not implemented here).

The outputs Yout, -(B-Y) and -(R-Y) are now AC coupled respectively at pin 8 (Y), pin 7 (R-Y) and pin 6 (B-Y) of the IC500 TDA4686 via the wire interconnection J800/J400 for further video processing.

The Yout, amplified by Q815, is now AC coupled at pin 8 of the TDA4686 (on RGB in+Driver module) via the current driver Q814 and via the wire interconnection J801/J236 for further video processing..

The outputs -(B-Y) and -(R-Y) are AC coupled respectively at pin 6 and pin 7 of the TDA4686 (on RGB in+Driver module) via the current drivers Q813 and Q812, the wire interconnection J801/J236, the inverting transistors Q245 and Q261 for further video processing.

### **B. SVideo .**

The +SVideo Voltage forward biases Q803 and Q808 to respectively "accept" the chrominance and luminance signals. This voltage automatically blocks Q807 and Q806 / Q804.

The flow is now the same as described before.

## ADJUSTMENT PROCEDURE QUAD DECODER 76 2224

### Preparation

- Switch the projector in the VIDEO MODE. Select source 1.
- Connect to the VIDEO input e.g. an electronic colour test video signal (see photo)

### Location of controls

### A. VIDEO INPUT SIGNAL :

*Pal Colour test image*

#### 1. Reference Oscillator C813

- if there is no colour, adjust trimming capacitor C813 until colour is being received.
- short-circuit pin 17 of IC800 to earth.
- adjust the trimming capacitor C813 for colour zero beat.
- remove the short-circuit.

#### 2. Chroma Rejector (L804) (photo 1)

- connect an oscilloscope to the emitter of transistor Q805 (Y signal).
- adjust the core of coil L804 for a minimum of chroma in the video signal.

#### 3. Chroma filter L801 (photo 2)

- connect the oscilloscope to the emitter of the transistor Q801 (R804).
- adjust the core of coil L801 for maximum chroma signal.

## B. VIDEO INPUT SIGNAL:

Secam Colour test image

### 4. Secam Reference circuit (L803 - P800) (photo 3 & 4)

- connect the oscilloscope to the capacitor C838 (B-Y) (pin 12 IC801).
- adjust L803 so that the level of the (B-Y) signal without colour information is the same as the level during blanking.
- connect the oscilloscope to the capacitor C839 (R-Y) (pin 11 IC801).
- adjust P800 so that the level of the (R-Y) signal without colour information is the same as the level during blanking.
- If necessary the level in (B-Y) channel has to readjust to zero with the coil.

### 5. BELL Filter L800 (photo 5)

- connect an oscilloscope to the emitter of Q800 (R804).
- adjust L800 for a flat amplitude of the signal during two successive lines.

## C. VIDEO INPUT SIGNAL :

NTSC 3.58 TEST IMAGE

### 6. Reference Oscillator C812

- If there is no colour, adjust trimming capacitor C812 until colour is being received.
- short circuit pin 17 of IC800 to earth.
- adjust trimming capacitor C812 for a colour zero beat.
- remove the short-circuit.

### 17. Chroma rejector L805 (refer to photo 1)

- connect the oscilloscope to the emitter of Q805 (R825).
- adjust the core of coil L805 for a minimum of chroma in the video signal.
